***PILOT'S OPERATING HANDBOOK  
AND  
FAA APPROVED AIRPLANE  
FLIGHT MANUAL***

Serial Number: \_\_\_\_\_

Registration Number: \_\_\_\_\_

Type Certificate No. A00003SE

THIS HANDBOOK INCLUDES THE MATERIAL REQUIRED TO BE FURNISHED TO THE PILOT BY THE FEDERAL AVIATION REGULATIONS AND ADDITIONAL INFORMATION PROVIDED BY THE MANUFACTURER, AND CONSTITUTES THE FAA APPROVED AIRPLANE FLIGHT MANUAL.

This Handbook meets GAMA Specification No. 1, *Specification for Pilot's Operating Handbook*, issued February 15, 1975 and revised September 1, 1984.

Approved by the Federal Aviation Administration

**POWERPLANT LIMITATIONS**

Number of Engines: One (1)

Engine Manufacturer: Teledyne Continental

Engine Model Number: TSO-550-C

Recommended Time Between Overhaul: 2000 Hours (Time in Service)

Maximum Power: 310 BHP at 2600 RPM

Maximum Manifold Pressure: 35.5 inches of Hg

Minimum Power Setting Above 18,000 ft.: 15 inches of Hg and 2200 RPM

Maximum Recommended Cruise: 262 BHP (85%)

Maximum Cylinder Head Temperature: 460°F (238°C)

Maximum Turbine Inlet Temperature: 1750°F (954°C)/1850°F (1010°C) for 30 sec.

**POWERPLANT FUEL AND OIL DATA****Oil Grades Recommended for Various Average Air Temperature Ranges**

Below 40°F (4°C) — SAE 30, 10W30, 15W50, or 20W50

Above 40°F (4°C) — SAE 50, 15W50, or 20W50

**Oil Temperature**

Maximum Allowable: 240°F (116°C)

Recommended takeoff minimum: 100°F (38°C)

Recommended flight operations: 170°F to 220°F (76.7°C to 104.4°C)

**Oil Pressures**

Normal Operations: 30-60 psi (pounds per square inch)

Idle, minimum: 10 psi

Maximum allowable (cold oil): 100 psi

**Approved Fuel Grades**

100LL Grade Aviation Fuel (Blue)

100 Grade Aviation Fuel (Green)

**Fuel Flow**

Normal Operations: 13 to 25 GPH (49 to 95 LPH)

Idle, minimum: 2 to 3 GPH (7 to 11 LPH)

Maximum allowable: 38.5 GPH (146 LPH)

**Vapor Suppression**

Required Usage:

- The Vapor Suppression rocker switch is required to be on above 18,000 ft.
- The Vapor Suppression rocker switch must be turned ON if TIT is rising above 1460°F at full power with the mixture full rich (at any altitude). Vapor suppression may be turned off below 18,000 ft if power has been reduced below 85% and engine temperatures have stabilized.

**POWERPLANT INSTRUMENT MARKINGS**

The following table, Figure 2 - 3, shows applicable color-coded ranges for the various powerplant instruments. The primary powerplant instruments are located on the engine instrument panel (see discussion on page 7-25). The Engine page on the MFD also displays all the powerplant instruments listed below (see discussion on page 7-141).

\* These temperatures or pressures are not marked on the gauge. However, it is important information that the pilot must be aware of.

† Range shown on analog gauge

‡ Range shown on MFD Engine page

Figure 2 - 3

**Crosswind Takeoff** – Crosswind takeoffs should be made with takeoff flaps. When the take off run is initiated, the aileron is fully deflected into the wind. As the airplane accelerates and control response becomes more positive, the aileron deflection should be reduced as necessary. Accelerate the airplane to approximately 75 knots, and then quickly lift the airplane off the ground. When airborne, turn the airplane into the wind as required to maintain alignment over the runway and in the climb out corridor. Maintain the best angle of climb speed (82 to 86 KIAS) until the airplane is clear of all obstacles. Once past all obstacles, accelerate to the best rate of climb speed (110 KIAS); at or above 400 feet AGL, raise the flaps.

### NORMAL AND MAXIMUM PERFORMANCE CLIMBS

**Best Rate of Climb Speeds** – The normal climb speed of the airplane, 110 KIAS, produces the most altitude gain in a given time period while allowing for proper engine cooling and good forward visibility. The best rate of climb airspeed is used in situations which require the most altitude gain in a given time period, such as after takeoff when an initial 2,000 feet or so height above the ground is desirable as a safety buffer. In another situation, ATC might require the fastest altitude change possible. The mixture should always be full rich in climbs.

**Cruise Climb** – Climbing at speeds above 115 KIAS is preferable, particularly when climbing to higher altitudes, i.e., those that require more than 6,000 feet of altitude change. A 500 FPM rate climb at cruise power provides better forward visibility and engine cooling. The engine should not be leaned during climb.

#### CAUTION

**Do not lean the engine during climb.**

**Best Angle of Climb Speeds** – The best angle of climb airspeed ( $V_x$ ) for the airplane is 82 KIAS at sea level to 86 KIAS at 10,000 feet, with flaps in the up position. The best angle of climb airspeed produces the maximum altitude change in a given distance and is used in a situation where clearance of obstructions is required. When using the best angle of climb airspeed, the rate at which the airplane approaches an obstruction is reduced, which allows more space in which to climb. For example, if a pilot is approaching the end of a canyon and must gain altitude, the appropriate  $V_x$  speed should be used. Variations in the  $V_x$  speeds from sea level to 10,000 feet are more or less linear, assuming ISA conditions.

**Power Settings** – Use maximum continuous power until the airplane reaches a safe altitude above the ground. Ensure the propeller RPM does not exceed the red line limitation. It is recommended to use full throttle and 2600 RPM in climb because this setting provides the engine with extra fuel for cooling at the slower airspeeds. When changing power, the sequence control usage is important. To decrease power, decrease manifold pressure first with the throttle control and then decrease RPM with the propeller control. The traditional practice of initially squaring power settings (for example, 25 in. MAP and 2500 RPM) is an acceptable procedure, but not required. The engine's turbochargers keep manifold pressure constant from MSL to approximately 18,000 ft.

#### NOTE

**During normal operations above 18,000 feet, a minimum engine condition of 2,200 RPM and 15 in.Hg of manifold air pressure are required to insure proper turbocharger operation is maintained. If engine operation below 15**

**in.Hg of manifold air pressure is necessary, the fuel mixture must be properly leaned or engine stoppage will result.**

**[WARNING]**

**Continuous overboost operation may damage the engine and require engine inspection.**

**Vapor Suppression** – The vapor suppression rocker switch must be turned on in the following situations:

- Operations above 18,000 ft.
- If TIT is rising above 1460°F at full power with the mixture full rich (at any altitude).

Once engine temperatures have stabilized and if the aircraft is below 18,000 ft, the vapor suppression switch may be turned off.

The vapor suppression switch should also be turned on any time the engine is not running smooth or it is suspected there is vapor in the lines. Vapor in the lines is most likely to happen in hot weather or at high altitudes.

**NORMAL OPERATIONS ABOVE 18,000 FT**

During normal cruise and descent operations above 18,000 ft., a minimum engine condition of 2200 RPM and 15 in.Hg of manifold air pressure are required to insure proper turbocharger operation is maintained. If engine operation below 15 in.Hg of manifold air pressure is necessary, the fuel mixture must be properly leaned or engine stoppage will result.

**CRUISE**

**Flight Planning** – Several considerations are necessary in selecting a cruise airspeed, power setting, and altitude. The primary issues are time, range, and fuel consumption. High cruise speeds shorten the time en route, but at the expense of decreased range and increased fuel consumption.

Cruising at higher altitudes increases true airspeed and improves fuel consumption, but the time and fuel used to reach the higher cruise altitude must be considered. Clearly, numerous factors are weighed to determine what altitude, airspeed, and power settings are optimal for a particular flight. Section 5 in this manual contains detailed information to assist the pilot in the flight planning process.

In general, the airplane cruises at 50% to 85% of available power. The maximum recommended cruise power setting is 85%. The minimum cruise power setting is 40%, but higher power settings may be required in colder weather to maintain minimum engine temperatures.

**Mixture Settings** – In cruise flight and cruise climb, care is needed to ensure that engine instrument indications are maintained within normal operating ranges. After reaching the desired altitude and engine temperatures stabilize (usually within five minutes), the mixture must be adjusted. The engine is equipped with an altitude sensing fuel pump which will automatically make some mixture adjustments for altitude effects, however additional adjustments may be required.

**Control by Turbine Inlet Temperature (TIT)** – When leaning the mixture using TIT, the pilot should use the aircraft's TIT gauge on the left hand kidney panel as primary. Be aware that the TIT displayed on the Avidyne MFD Engine page, under certain conditions, may indicate a higher value. If this occurs the pilot may wish to use the most conservative (higher) number for leaning the engine. At power settings below 85% power, starting at full rich mixture, lean slowly while observing the TIT. When changing the mixture to lean of peak, it is acceptable to have TIT indications temporarily in the yellow range, but indications must return to the normal range upon leaning completion. Best power is obtained at 1650°F rich of peak. The engine can be leaned past peak and be operated 50°F lean of peak TIT. Lean of peak operation improves the efficiency of the airplane and provides about 30°F lower CHT at the same RPM/MAP combination. Fuel flow can be used as a reference to judge the resulting power setting, but should not be used for leaning.

**CAUTION**

**Do not lean the engine when operating above 85% power. At power settings above 85%, the mixture must be full rich. Do not lean the engine during climb.**

**CAUTION**

**To prevent detonation, when increasing power, enrich mixture, advance RPM, and adjust throttle setting, in that order. When reducing power, retard throttle, then adjust RPM and mixture.**

**CAUTION**

**When leaning the mixture, it is acceptable to have TIT indications temporarily in the yellow range to detect peak. Once leaning is complete, the temperatures are in the normal range.**

**WARNING**

**Continuous overboost operation may damage the engine and require engine inspection.**

**Door Seals** – Normally, the door seal switch remains in the On position for the entire flight. If the system pressure drops below 12 psi, the air pump will cycle on until pressure is restored. If the pump runs continuously, it is an indication that a seal is damaged and incapable of holding pressure. In this situation, the door seal system should not be operated until repairs are made.

**Inoperative Door Seal Dump Valve** – If the door seal dump valve should fail, the door seal system can still be operated. However, the door seals must not be turned on until after takeoff and must be turned off before landing. This procedure ensures rapid egress from the airplane in an emergency situation. Moreover, opening the doors with the seals inflated can damage the inflatable gaskets. For more information on the door seals and dump valve refer to page 7-18.

**DESCENT**

The primary considerations during the descent phase of the flight are to maintain the engine temperatures within normal indications and to systematically increase mixture settings as altitude is decreased. The descent from altitude is best performed through gradual power reductions and gradual enrichment of the mixture. Avoid long descents at low manifold pressure as the engine

## **CRUISE PERFORMANCE OVERVIEW**

The tables on pages 5-15 through 5-28 contain cruise data to assist in the flight planning process. This information is tabulated for even thousand altitude increments and ranges from Sea Level feet to 25,000 feet. Interpolation is required for the odd number altitudes, i.e., 5000 feet, 7000 feet, etc., as well as altitude increments of 500 feet, such as 7500 and 9500.

The tables assume proper leaning at the various operating horsepowers. Between 65% and 85% of brake horsepower, the mixtures should be leaned through use of the turbine inlet temperature (TIT) gauge. Please refer to page 4-30 in this handbook for proper leaning techniques.

KTAS values in the tables are valid without the nose wheel pant installed. If the nose wheel pant is installed add 4 kts to the KTAS values.

The maximum recommended cruise setting is 85% of brake horsepower. The mixture must not be leaned above settings that produce more than 85% of brake horsepower. During cruise power settings above 65%, ambient temperature conditions need to be considered. In hot weather and high altitudes, it may be necessary to set the fuel flow to a lower TIT to maintain cylinder head temperatures within the recommended range for cruise.

Cessna 400 (LC41-550FG)

### EXAMPLE PROBLEM AND SOLUTION

#### Conditions

Cruise Altitude ..... 2000 feet  
Temperature ..... 22°C  
Manifold Pressure ..... 29 inch Hg  
RPM ..... 2700

#### Solution

% of BHP ..... 73%  
Fuel Consumption ..... 18.5 GPH (73 LPH)  
True Airspeed ..... 177.5 Knots

#### Determine

1. ..... % of BHP
2. ..... Fuel Consumption (GPH)
3. ..... True Airspeed

3600 lbs. (1633 kg) Gross Weight

Recommended Mixture Setting. Data in these charts are based on this leaning schedule discussed on page 4-30.  
Best Power**EXAMPLE PROBLEM AND SOLUTION****Conditions**

Cruise Altitude ..... 4000 feet  
 Temperature ..... -9°C  
 Manifold Pressure..... 33 inch Hg  
 RPM ..... 2400

**Solution**

% of BHP ..... 87%  
 Fuel Consumption ..... 24.5 GPH (92 LPH)  
 True Airspeed..... 188 Knots\*

**Determine**

1. ..... % of BHP
2. ..... Fuel Consumption (GPH)
3. ..... True Airspeed

\*As a rule, always round to the more conservative number when using the various performance tables in this handbook.

### EXAMPLE PROBLEM AND SOLUTION

#### Conditions

Cruise Altitude ..... 6000 feet  
Temperature ..... 33°C  
Manifold Pressure ..... 23 inch Hg  
RPM ..... 2500

#### Solution

% of BHP ..... 49%  
Fuel Consumption ..... 12.5 GPH (48.0 LPH)  
True Airspeed ..... 161 Knots

#### Determine

1. ..... % of BHP
2. ..... Fuel Consumption (GPH)
3. ..... True Airspeed

3600 lbs. (1633 kg) Gross Weight

Recommended Mixture Setting. Data in these charts are based on this leaning schedule discussed on page 4-30.  
Best Power**EXAMPLE PROBLEM AND SOLUTION****Conditions**

Cruise Altitude ..... 8000 feet  
 Temperature ..... -2°C  
 Manifold Pressure..... 29 inch Hg  
 RPM ..... 2500

**Solution**

% of BHP ..... 86%\*  
 Fuel Consumption ..... 25 GPH (93 LPH)  
 True Airspeed..... 196 Knots

**Determine**

1. ..... % of BHP
2. ..... Fuel Consumption (GPH)
3. ..... True Airspeed

\*This power setting is above the maximum recommended cruise setting of 85% and does not represent a recommended mixture setting.

### EXAMPLE PROBLEM AND SOLUTION

#### Conditions

Cruise Altitude ..... 9000 feet  
Temperature ..... -9°C  
Manifold Pressure ..... 29 inch Hg  
RPM ..... 2500

#### Solution

% of BHP ..... 77%  
Fuel Consumption ..... 21 GPH (79 LPH)  
True Airspeed ..... 194 Knots

#### Determine

1. ..... % of BHP
2. ..... Fuel Consumption (GPH)
3. ..... True Airspeed

Figure 5 - 28

## LEAN OF PEAK ENGINE OPERATION

The TSIO-550C engine can be operated lean of peak at lower power settings. At higher power settings the TIT limit could be exceeded during the leaning process, in general leaning past peak TIT is only possible below about 65% power (varies with ambient conditions). The Avidyne MFD will not show a reduction in % power during the leaning process even though it changes. Starting from full rich, the power increases about 1% as "Best Power" mixture is reached. For cruise operation, best power is at or near 1650°F TIT rich of peak. If the mixture is leaned further past peak EGT (TIT), the power drops 8-12%. "Best Economy" is reached at about 50°F lean of peak. Because of the drop in power, speed will be reduced even though the MFD will show the same % power. Once a lean of peak mixture setting is reached, the rpm and manifold pressure can be increased carefully. By increasing the manifold pressure while operating lean of peak (do not exceed 29 in.Hg), the power loss from leaning can be compensated. For continuous operation, TIT should be at or below 1650°F. Figure 5 - 30 below shows a comparison of fuel flows for best power and best economy and is valid for one rpm (about 2400 rpm). At higher rpm the fuel flow is slightly higher or slightly lower at lower rpm respectively. The power setting in Figure 5 - 30 is actual power and not the MFD indication in the case of the lean of peak curve.
