Vicki Chlanda Research Chemist	John Calvin System/Component Analyst	Bob Moran Director, Product Integrity
Don Parker Technical Associate		

D. DETAILS OF EXAMINATION

1.0 General

Testing of hydraulic fluid samples from USAir flight 427 and other airplanes occurred at the Queeny Plant and the Corporate Research laboratories of Monsanto Co. in St Louis, Missouri, the chemical laboratories of Tinker Air Force Base Oklahoma City, Oklahoma, and at the Customer Support laboratories for Parker Bertea Aerospace (Parker) in Irvine, California. Analyses were performed in accordance with BMS 3-11J[1], ARP 598B[2],

applicable ASTM[3] standards or under the direction of the Hydraulic Fluids Sub Group. Particle contamination classifications were based on the rating system established by NAS 1638[4]. Boeing 737 series airplanes use hydraulic fluid in compliance with BMS 3-11 Type IV. At present there are two qualified manufacturers of BMS 3-11, Type IV fluid, Monsanto which makes Skydrol LD-4 and Skydrol 500B-4, and Chevron, which produces Hyjet IV-A^{Plus}. Boeing originally delivered N513AU with Hyjet IV-A hydraulic fluid, which is no longer produced. USAir presently uses Skydrol LD-4 fluid.

2.0 Analytical Procedures

2.1 Wet Chemical Analyses

The Monsanto Queeny laboratory conducted wet chemical analyses. After visual inspection for color and clarity, the samples were analyzed for percent water content (ASTM D-1744), acid number (ASTM D-974-87), specific gravity (Calculating Density Meter Mettler DMA46), and chlorine content (Dohrman MCTS-120 Automated Chlorine Analyzer). Each sample was also analyzed by gas chromatography (GC).

2.2 Particle Count Analysis by Laser-Light Scattering Technique

Particle counts were determined on samples using an automated laser light-scattering method. Samples were mechanically agitated for six minutes just prior to measurement to ensure homogeneity. A HIAC/Royco model 8000A was used to measure particle levels in five particle size ranges, as defined in NAS 1638. Fluid samples were retained in their original bottles throughout this procedure in order to minimize inadvertent contamination.

Approximately 50 ml of sample was consumed in this test. All automatic particle count results reported have been are normalized to 100 ml sample size. Particle contamination results and class ratings per NAS 1638 are reported in attached tables.

2.3 Particle Count Analysis by Manual Counting Method

Manual particle counting was conducted on fluid samples that had insufficient volume for the automatic laser light-scattering technique. Fluid samples were analyzed per Aerospace Recommended Practice 598B (ARP 598B) at either Tinker Air Force Base, Oklahoma City, Oklahoma, or the Parker laboratory, Irvine, California. Tinker Air Force

[4]National Aerospace Standard published Jan, 1964 by the Aerospace Industries Association of America, Inc.

Base used Millipore cellulose nitrate filter elements (Type AA, 0.8 um pore size). These filters were noted to locally darken and fragment after filtering Skydrol fluids. Parker used polysulfone filter elements (0.8 um pore size).

The entire available fluid volume was used in the manual particle count analyses. After filtering the fluid sample into precleaned glassware, the sample bottle was rinsed thoroughly with precleaned solvent and the solvent filtered through the filter element. The original sample volume was calculated by subtracting the tare weight of the bottle from the gross weight of the bottle and fluid sample, then multiplying by 1.05 to account for the specific gravity of the fluid. All manual particle count results reported have been normalized to a 100 ml sample size. Particle contamination results and class ratings per NAS 1638 are reported in Appendices.

2.4 Microscopy Sample Preparation

Hydraulic fluid samples #39, #40, #56, #59, #64, #65, #68, and #71 were prepared for analysis by hand shaking each sample for 30 seconds, removing 10 ml of fluid, filtering using a Poretics polycarbonate membrane filter (0.8 um pore size), and rinsing with 10 ml of acetone. Samples #51 and #52 were prepared by adding ~3 ml of Skydrol LD-4, ultrasonicating, filtering using a Poretics membrane, rinsing with additional Skydrol and then with acetone. The remaining samples analyzed for composition at the research laboratories of Monsanto had been filtered at either Tinker AFB or Parker prior to submission.

2.5 Particle Characterization by Fourier Transform Infrared (FTIR) Microscopy

FTIR was performed at Monsanto Corporate Research laboratories on selected particles to determine compound information. A few particles were removed from each filter pad and placed on the surface of individual potassium bromide (KBr) crystals, an inert substrate. Representative particles were selected based on differing visual appearances and not all of the particles from any given sample were analyzed. Infrared spectra were then acquired using a Spectra-Tech microscope coupled to a Nicolet 800 FTIR spectrometer. Data were collected from 3800 cm^{-1} to 700 cm^{-1} at 4 cm^{-1} resolution, co-adding 128 scans.

2.6 Particle Characterization by Electron Probe Microscopy

Scanning electron microscopy/electron probe microanalysis was performed on selected filter sections at Monsanto Corporate Research laboratories to provide surface images and elemental detection on the filtered particles. Subsequent to FTIR examination, a random portion of each filter element, not to exceed 25% of the filter area, was selected for examination by this technique. A Cameca MicroBeam system having both surface imaging (back scatter electron) and element detection (energy dispersive) capabilities was used for data collection. Three representative areas of the isolated filter were examined at

200 times magnification. For each representative area, a back scatter surface image and a series of element specific images (dot maps) were collected.

3.0 As-received Fluid Samples

Three groups of samples were received and analyzed.

1. In-service samples from three airlines (referenced as in-service samples).
2. Rudder power control unit (RPCU) samples removed from six PCU's received at Parker for service (referenced as in-service RPCU samples).
3. Samples from the accident aircraft, further divided into two sub sets.
   i. From the rudder PCU (referenced as accident PCU samples).
   ii. From other components of the airplane (referenced as other accident samples).

Sample sizes varied with the in-service samples and the B link cavity RPCU samples containing about 200 milliliters (ml) each and the remaining samples were, in general, less than 100 ml. The volume of sample was the main determining factor in establishing the type and number of individual analyses on many of the samples. Sample collection protocols were not reported for the Southwest and United Airline samples. USAir in service samples were reportedly obtained following the instructions set forth in USAir Campaign Directive No. 29H00801.

Individual samples and data sets were assigned a discrete integer sample number (XX) as they were received. Additional or duplicate test data were assigned a decimal extension on the basic sample number (XX.X).

3.1 In-Service Sample Analysis

Analyses were performed on 104 in-service samples of fluid from 21 airplanes. Each airplane was sampled at four locations: "A system reservoir", "A system rudder PCU return", "B system reservoir" and "B system rudder PCU return". Eleven of the airplanes were from the USAir fleet (sample #1 through #44) five from Southwest Airlines (#74 through #113) and five from United airlines (#114 through #133). Two samples from each sample point were received from Southwest Airlines. See Table A for test data and results.

An automatic laser light-scattering particle counting method was performed on all of the in-service samples. The particle count data were converted to particle contamination class ratings for each size range and an overall fluid class was assigned per NAS 1638. For example, a fluid that contained class 5, 6, 7, 8 and 9 contamination in the five measured size ranges is considered to be a class 9 fluid.

From the classification data it was determined that, in total, the in-service samples ranged from a class 1 to class 13 and had a mean fluid classification of 7.5[5]. The fluid class

[5]Standard deviation 1.95

data from USAir averaged 7.6 with Southwest and United fluids averaging 8.5 and 5.7, respectively[6].

Wet chemical analyses were performed on the in-service samples from each airplane. The test results are presented in Table A. All of the samples met the applicable limits set for a new fluid in BMS 3-11.

Each of these samples were analyzed by gas chromatography (GC) to detect other fluid contaminates, such as jet fuel or lubricating oils. This method also determined the relative content of Skydrol and Hyjet in the sample. None of the in-service samples were found to be contaminated with other fluids.

3.2 In-service RPCU samples

Two fluid samples were removed upstream of the filters and one from the link cavity of each of the six in-service RPCU's. These samples were labeled as being from the "large filter", "yaw damper filter" and the "B system link cavity" and are listed in Table B as samples #56 through #73. The B link cavity samples were each in excess of 150 ml while the samples from upstream of the large filter and the yaw damper filter were all less than 100 ml. Automatic particle counts and GC analysis were performed on the six samples from the B system link cavities of the in-service RPCUs. Due to sample size limitations, the particulate contamination levels for these samples were determined by the manual count method as described above.

Ten samples (#56 through #65) from four of the in-service RPCUs were filtered and counted at Tinker AFB and eight samples (#66 through #73) were filtered and manually counted at Parker. In addition to samples #66 through #73, Parker manually counted one sample (#65) that had been previously filtered and counted at Tinker AFB.

3.3 Samples from the Accident Airplane

3.31 Samples from the Accident Airplane Rudder PCU

On September 29, 1994[7] six hydraulic fluid samples from the accident airplane and one sample from the Parker hydraulic test stand were analyzed at Monsanto's fluids laboratory. Two of these samples (#138 and #139) were from the standby rudder PCU and were reportedly completely consumed in testing. Sample #139 had been intentionally spiked by the NTSB with a small quantity of chlorine bleach prior to analysis. The results of the tests for this sample were therefore invalidated. The remaining liquid portions of these samples were retained and further analyzed as samples #51 through #55. After automatic particle counting, samples #51 and #52 were centrifuged in an attempt to separate the particles. During the separation process the samples were inadvertently contaminated by

[6]Standard deviations of 1.74 for USAir, 1.78 for Southwest and 1.30 for United.

[7]Prior to the formation of the Hydraulic Fluid Sub Group.

material that was later determined to be polystyrene. The polystyrene contamination was subsequently removed by filtering the samples and flushing with clean filtered Skydrol. The particle contamination in samples #53, #54 and #55 were measured and classified by manual counting.

In addition to the above listed samples, four samples from the accident RPCU were retained at Parker. These samples (#134 through #137) were filtered and manually counted by Parker. Unfortunately, the count method did not follow the particle size ranges listed in ARP 598 and NAS 1638 and were therefore not comparable.

3.32 Other Accident Samples

Fluid samples were also received from other components on the aircraft, identified in Table C. These are identified in Appendix C as samples #45 through #50. Due to the possibility of artifacts introduced by the reported extensive fire and mechanical damage and to the reported extensive disassembly necessary for fluid sample retrieval, these samples were retained but not subjected to particle counting. Gas chromatography spectra were acquired from all samples and specific gravity measurements were made on samples #45, #46, #48 and #50.

3.4 Particle Identification on Accident Samples

The filtered particles from several selected samples were subjected to FTIR and EDS as described in the Analytical Procedures section above. The selected samples included two from the in-service group (#39 and #40), eight from USAir flight 427 (#51, #52, #53, #55, #134, #135, #136 and #137) and eleven from the link cavities of the in-service RPCUs (#56, #57, #58, #59, #60, #61, #62, #63 #64, #65, #68 and #71). Classifications for the analyzed particle types are presented in Table D. Due to the complexity of FTIR spectra, matches to specific chemical compounds were not always possible, in which case the generic chemical group of type was listed in the table. For the particles subjected to EDS analysis, the table listing show elements identified in each particle type but not their relative percentage concentrations.
